

# Web Development Fundamentals

Lists Revision

HTML - Links

Lecturer: Marie Brennan

# lists

```
<ol>  
  <li>Coffee</li>  
  <li>Tea</li>  
  <li>Milk</li>  
</ol>
```

## **Ordered List**

1. Coffee
2. Tea
3. Milk

# Roman numerals

```
<ol type="i">  
  <li>Coffee</li>  
  <li>Tea</li>  
  <li>Milk</li>  
</ol>
```

- i. Coffee
- ii. Tea
- iii. Milk

# letters

- `<ol type="A">`
- `<li>Coffee</li>`
- `<li>Tea</li>`
- `<li>Milk</li>`
- `</ol>`

## **Ordered List with Letters**

- A. Coffee
- B. Tea
- C. Milk

# Styles

○ `<ul style="list-style-type:disc">`  
    `<li>Coffee</li>`  
    `<li>Tea</li>`  
    `<li>Milk</li>`  
`</ul>`

## **Unordered List with Disc Bullets**

- Coffee
- Tea
- Milk

# Removing the numbers

○ `<ul style="list-style-type:none">`  
    `<li>Coffee</li>`  
    `<li>Tea</li>`  
    `<li>Milk</li>`  
    `</ul>`

## Unordered List without Bullets

Coffee  
Tea  
Milk

# Changing the style in html

- `<ul style="list-style-type:square">`
- `<li>Coffee</li>`
- `<li>Tea</li>`
- `<li>Milk</li>`
- `</ul>`

## Unordered List with Square Bullets

- Coffee
- Tea
- Milk

# Changing the style in html

○ `<ul style="list-style-type:circle">`  
    `<li>Coffee</li>`  
    `<li>Tea</li>`  
    `<li>Milk</li>`  
`</ul>`

## Unordered List with Circle Bullets

- Coffee
- Tea
- Milk

# HTML Description Lists

HTML also supports description lists.

A description list is a list of terms, with a description of each term.

The `<dl>` tag defines the description list, the `<dt>` tag defines the term (name), and the `<dd>` tag describes each term:

Example

```
<dl>
  <dt>Coffee</dt>
    <dd>- black hot drink</dd>
  <dt>Milk</dt>
    <dd>- white cold drink</dd>
</dl>
```

## A Description List

Coffee  
- black hot drink  
Milk  
- white cold drink

# Nested lists

```
<ul>  
  <li>Coffee</li>  
  <li>Tea  
    <ul>  
      <li>Black tea</li>  
      <li>Green tea</li>  
    </ul>  
  </li>  
  <li>Milk</li>  
</ul>
```

## A Nested List

- Coffee
- Tea
  - Black tea
  - Green tea
- Milk

# Linking pages

# Introduction

- This week we are going learning how to add an important features to web pages:
- hypertext *links*
  - This allows us to make sites, comprising of multiple interlinked pages, and also link to pages on other web sites on the WWW
- Plus we'll learn a bit more about images ...

# Adding Links - Introduction

- If you are creating a page for the web, chances are you will want it to link somewhere.
- These are the main examples of where to link:
  1. Link to another page of your site
  2. Link to a page on someone else's site
- To create a link we use the *anchor* element, **a**
  - I know, this is a terrible name ... but at least it's short
- This comprises of an opening and closing tag e.g.
  - `<a> ... </a>`

# The href Attribute

- The href attribute provides the address (URL) of the page we want to link to.
- The URL must always be in quotation marks.
- In fact, the values of *all* attributes should be in quotation marks.
- Most of the time we link to other HTML documents.
- But, we can also link to resources such as images, video files, audio and so on.
- There are two different ways to specify the URL.

# Adding Links - Introduction

- The content of this element becomes the hypertext link
- Wrap some text in opening and closing `<a>...</a>` tags and use the `href` attribute to provide the URL of the linked page.

- For example:

`<a href="http://www.itb.ie">ITB</a>`

- This links to ITB's website
- Appear in browser as text "ITB", blue and underlined
  - if no other style rules are applied to the page

# Adding Links - Introduction

- Can use **IMAGES** as content for links
- Or mixture of images and text
- There is NO restriction on what can be the content inside an anchor link element
  - **Text**
  - **Images**
  - Mixed text and images
  - Block level elements like paragraphs etc...not very common though

# The href Attribute

- The href attribute provides the address (URL) of the page we want to link to.
- The URL must always be in quotation marks.
- In fact, the values of *all* attributes should be in quotation marks – KIS (Keep is Simple ...)
  - (this is best practice, since it means you don't have to worry about when they MUST be used and when they are optional ...)
- Most of the time we link to other HTML documents.
- But, we can also link to resources such as images, video files, audio and so on.
- There are two different ways to specify the URL.

# Absolute URLs: link to another website

## Absolute URLs

- These provide the full URL for the document
- This includes:
  - The protocol (http://)
  - The domain name
  - The pathname
- You have to use the absolute URL when pointing to a page that is out on the Web.
- For example:
- href =  
"http://www.itb.ie/CurrentStudents/index.html"

## Absolute URLs:

### Linking to Pages on the Web

- A link to a page on another site called an *external* link.
- Have to use absolute URL for this, which includes:
  - **protocol**                      http://
  - **Site name**                      www.itb.ie
  - **Pathname**                      /CurrentStudents/index.htm
- The next slide contains some HTML code with some examples of internal links.

# Relative URLs:

## link to another page on same website

### Relative URLs

- These describe the pathname to the linked file *relative* to the current document.
- No protocol, no domain name. Just use the pathname.
- Relative URLs are used when linking to pages on your own site (i.e. on the same server)
- For example:

`href = "about.html"`

`href = "contact.html"`

- Can also link to sub-folders ...

`href = "courses/computing.html"`

## Linking to Pages on the Web

```
<!DOCTYPE html>
<html lang="en"><head>
  <meta charset="utf-8">
  <title>Links Example</title>
</head>
```

```
<body>
```

```
<p>
```

An example of a good site about web design and development is

[A List Apart](http://www.alistapart.com).

```
</p>
```

```
<p>
```

It contains information on all sorts of topics, including:

```
</p>
```

```
<ul>
```

```
<li><a href="http://www.alistapart.com/topics/code">Code</a></li>
```

```
<li><a
```

```
href="http://www.alistapart.com/topics/content">Content</a></li>
```

```
<li><a
```

```
href="http://www.alistapart.com/topics/design">Design</a></li>
```

```
</ul>
```

```
</body>
```

```
</html>
```

# Linking to Pages on the Web

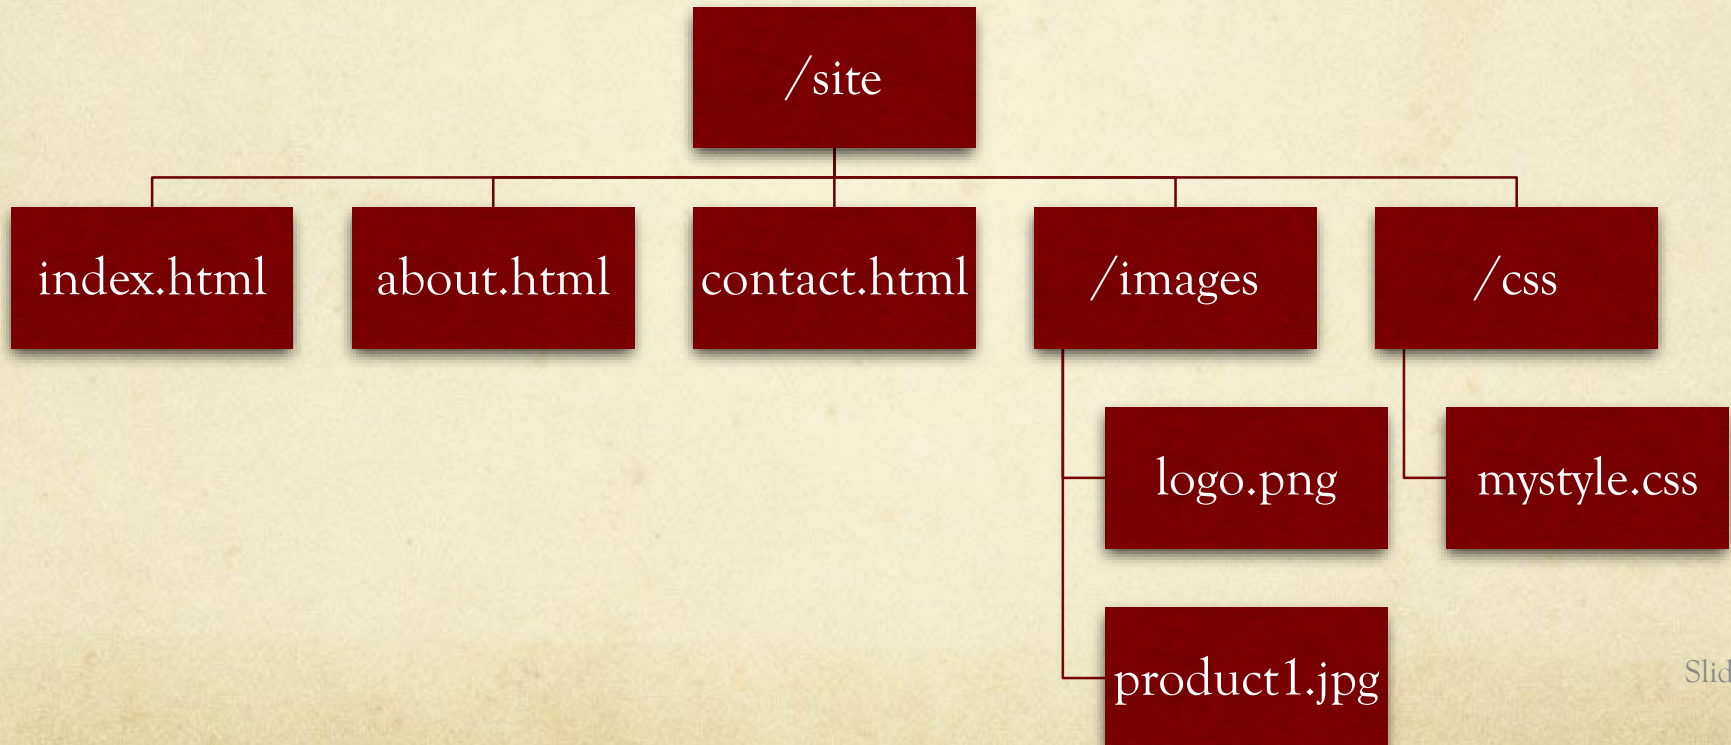

# Linking Within Your Own Site

- Most linking will be to pages within same site
- In these cases, we use a *relative* URL
  - one that calls for a page within your own server
  - you do NOT specify the protocol for relative URLs
- browser looks for file on current server
  - i.e. same server as webpage in which link is written
- VERY simple, if website designed carefully, e.g.:
  - **index.html**
  - **about.html**
  - **contact.html**
  - **products.html**
  - **Plus folders /images and /css**

# Simple website structure

- Sub-folder for images
- Sub-folder for CSS style sheets
- All HTML pages in main website folder

## Relative URLs:

### Linking within same directory/folder

- Simplest relative URL is when we want to link to another file within same directory/folder
- Just write filename of file to link to
- For example, if want to link from `index.html` to the file `about.html`.
  - Both files are in the same directory.
  - So, the link inside `index.html` would be as follows:

`<a href="about.html">About Page</a>`

- See diagram on next slide

## Jen's Kitchen

### Welcome to Jen's Kitchen

People who know me know that I love to cook. I've created this site to share some of my favorite recipes and online food resources.  
*Bon appetit!*

Visit the site

#### Items in Jen's Cookbook

- Tapenade (Olive Spread)
- Garlic Salmon
- Linguine with Clam Sauce
- Couscous with Peas and Mint

#### Good Food on the Web

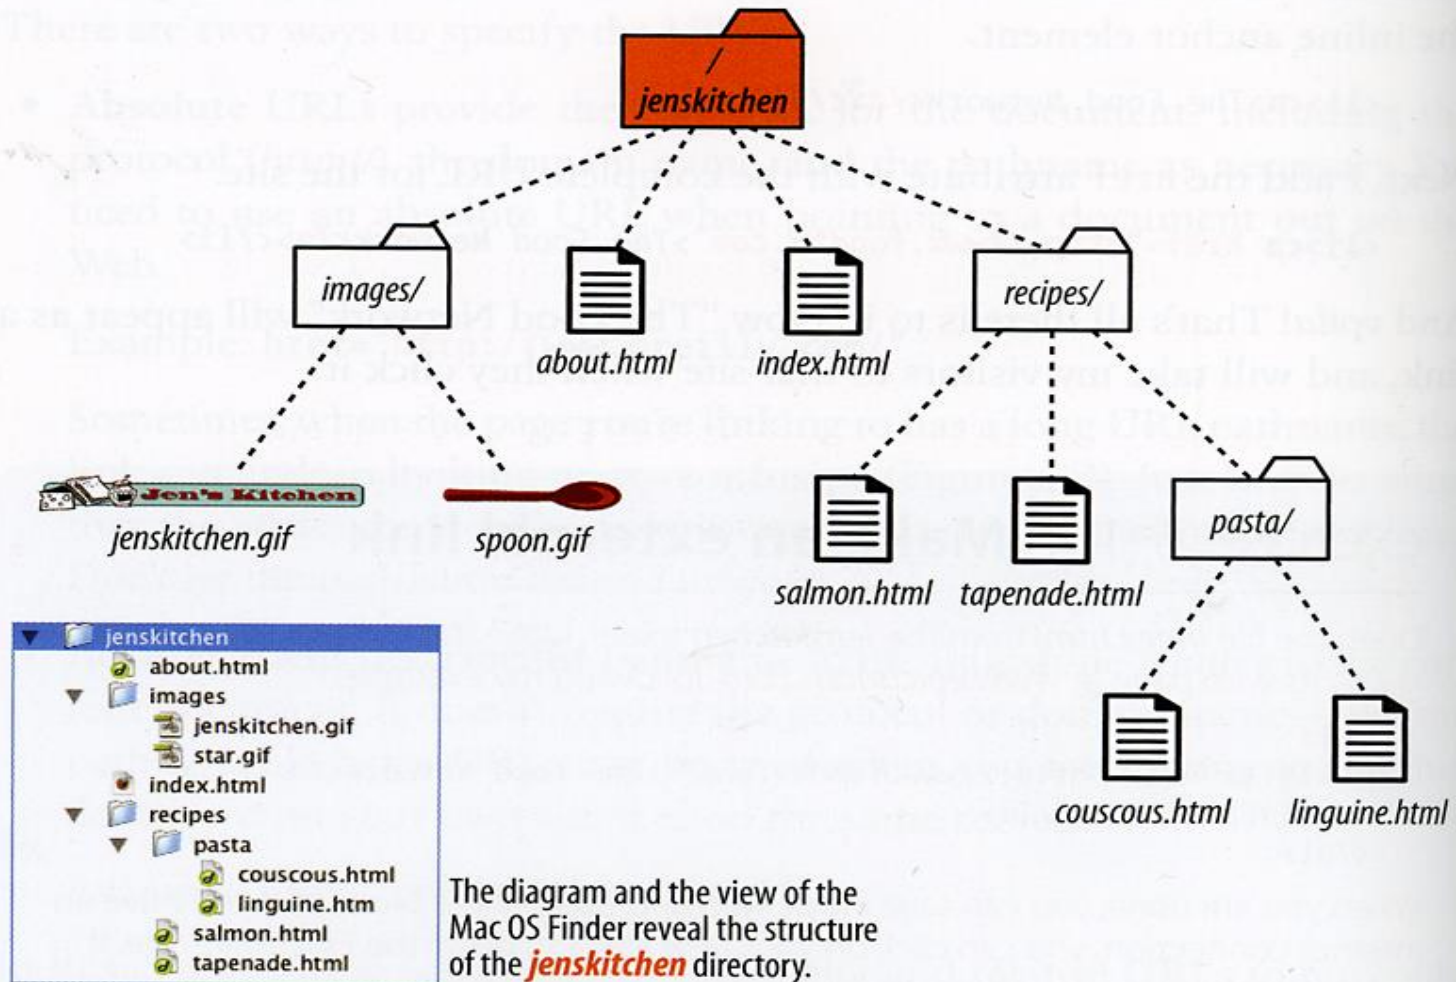

- The Food Network
- Epicurious

Copyright 2006, Jennifer Robbins

# Sample Website

# Linking Within Your Own Site – structure of the site

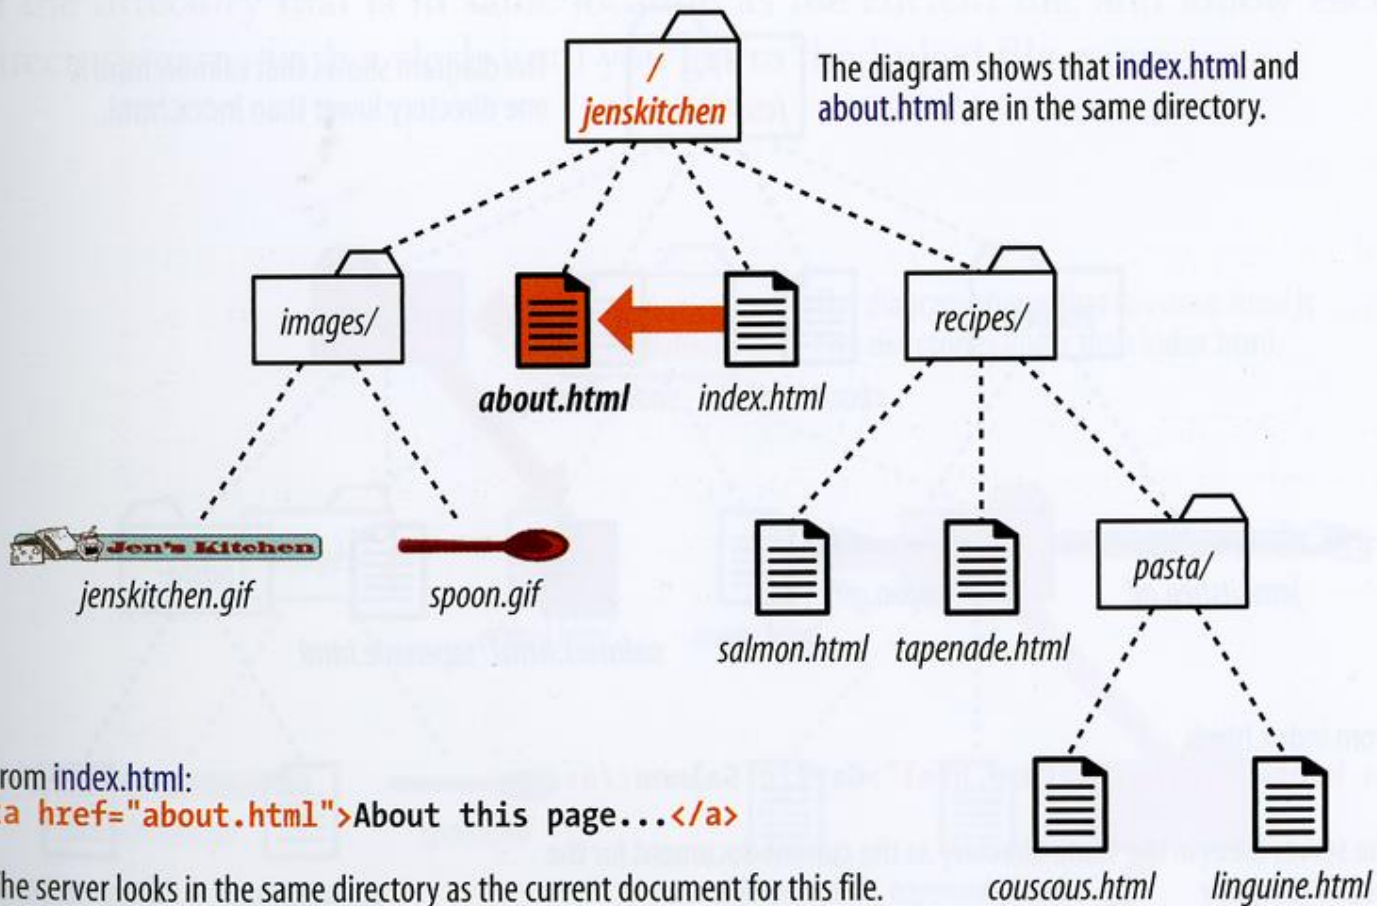

# Structure of the Site

- So the site is contained within a folder called **jenskitchen**.
- This folder contains an **index.html** file and an **about.html** file.
- It also contains the folders **images** and **recipes**.
  - The **images** folder contains all the graphic image files for the site. This is a common enough convention for websites.
- The **recipes** folder contains two html files and another folder called **pasta**.
- The **pasta** folder contains the files **couscous.html** and **linguine.html**.

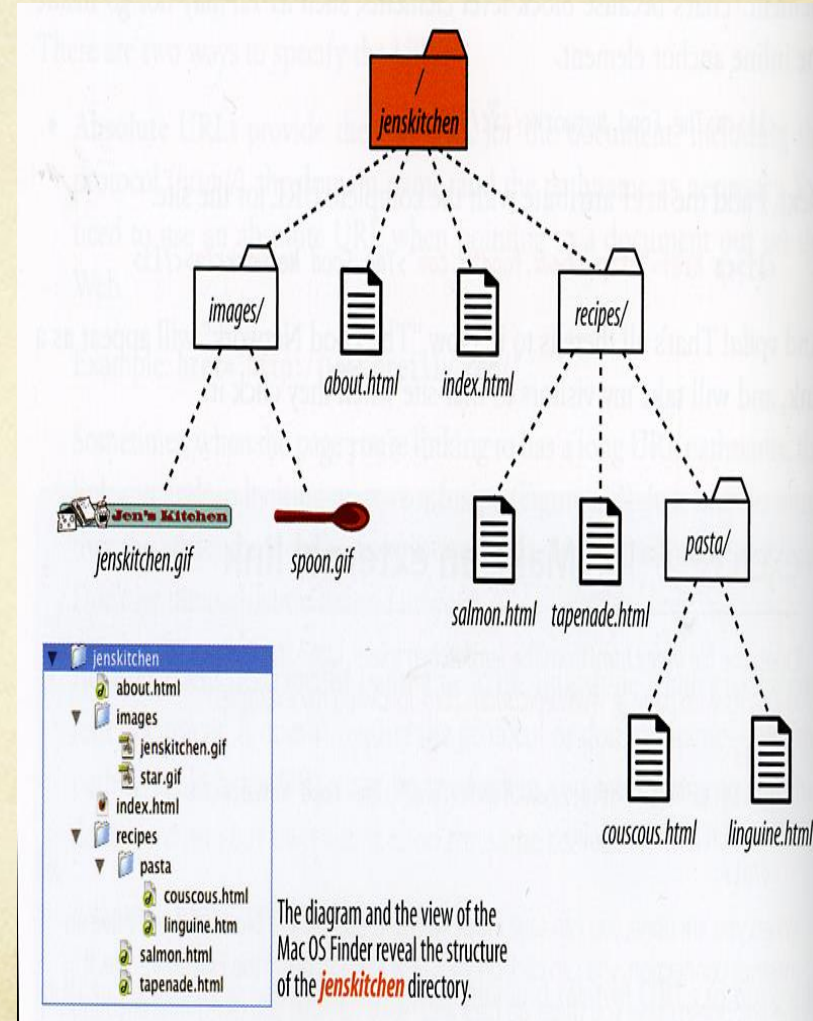

# Linking Within Your Own Site

**Figure 6-5.** Writing a relative URL to another document in the same directory.

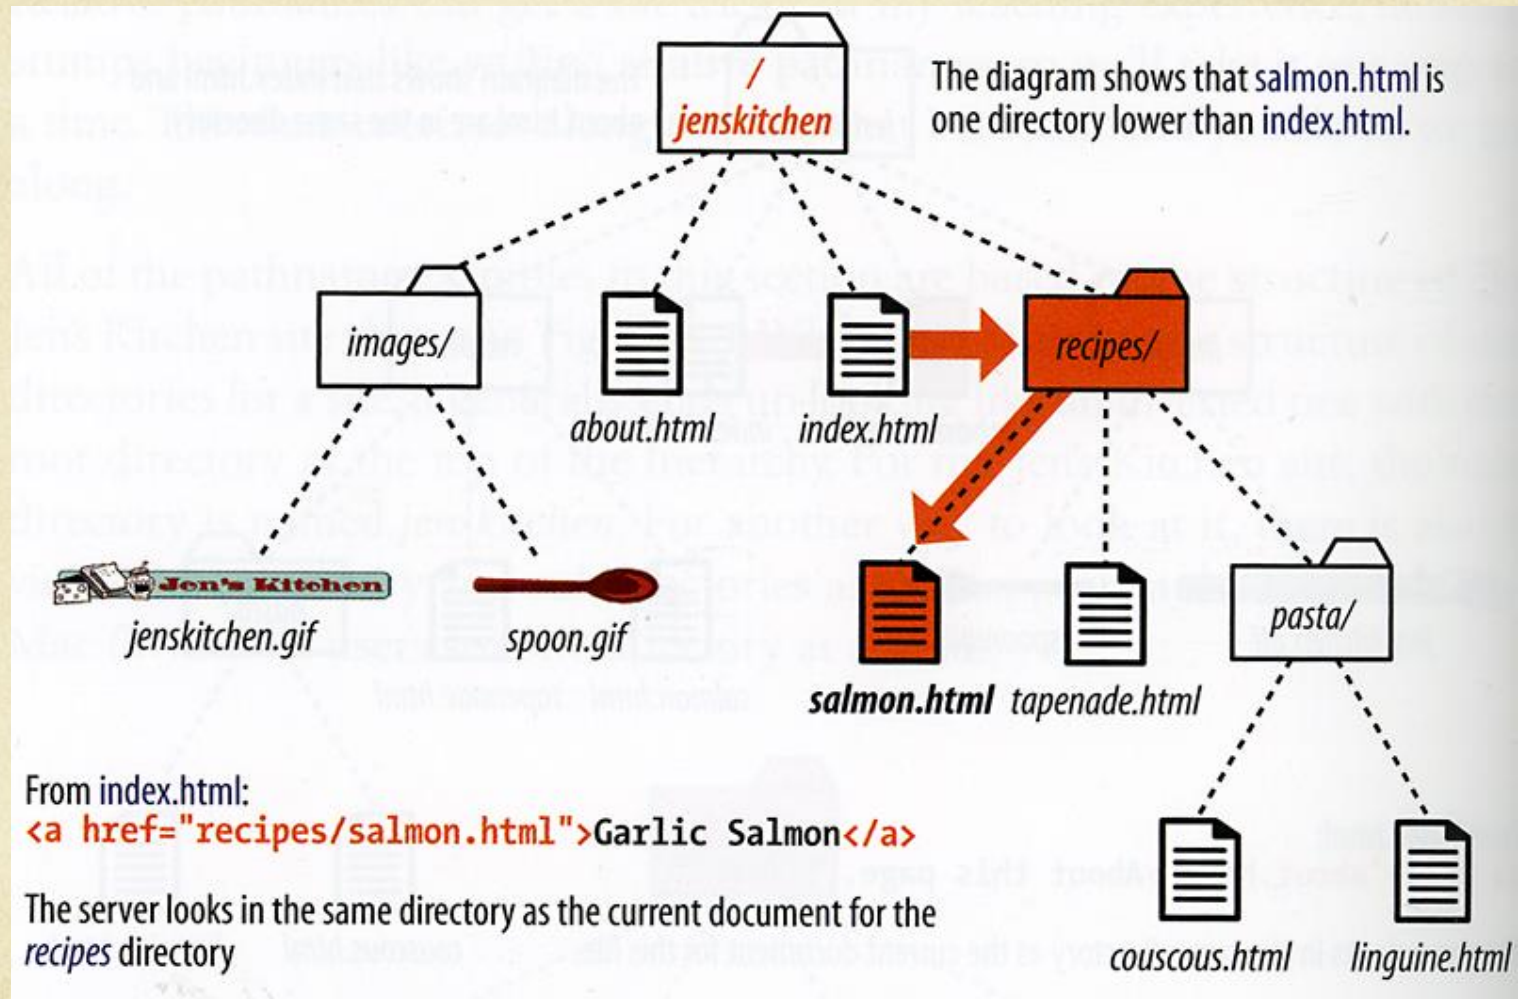

# Linking to a Lower Directory

- What if the files are not in the same directory?
- In this case we need to provide a pathname so the browser knows where to look in the file hierarchy.
- Suppose for example, we want to link from `index.html` to `salmon.html`.
- `salmon.html` is in the directory `recipes`.
- So the pathname needs to tell the browser to look in the current directory for a directory called `recipes`, and then look inside *that* for the file `salmon.html`.
- `<a href="recipes/salmon.html">Garlic Salmon</a>`

# Linking Within Your Own Site

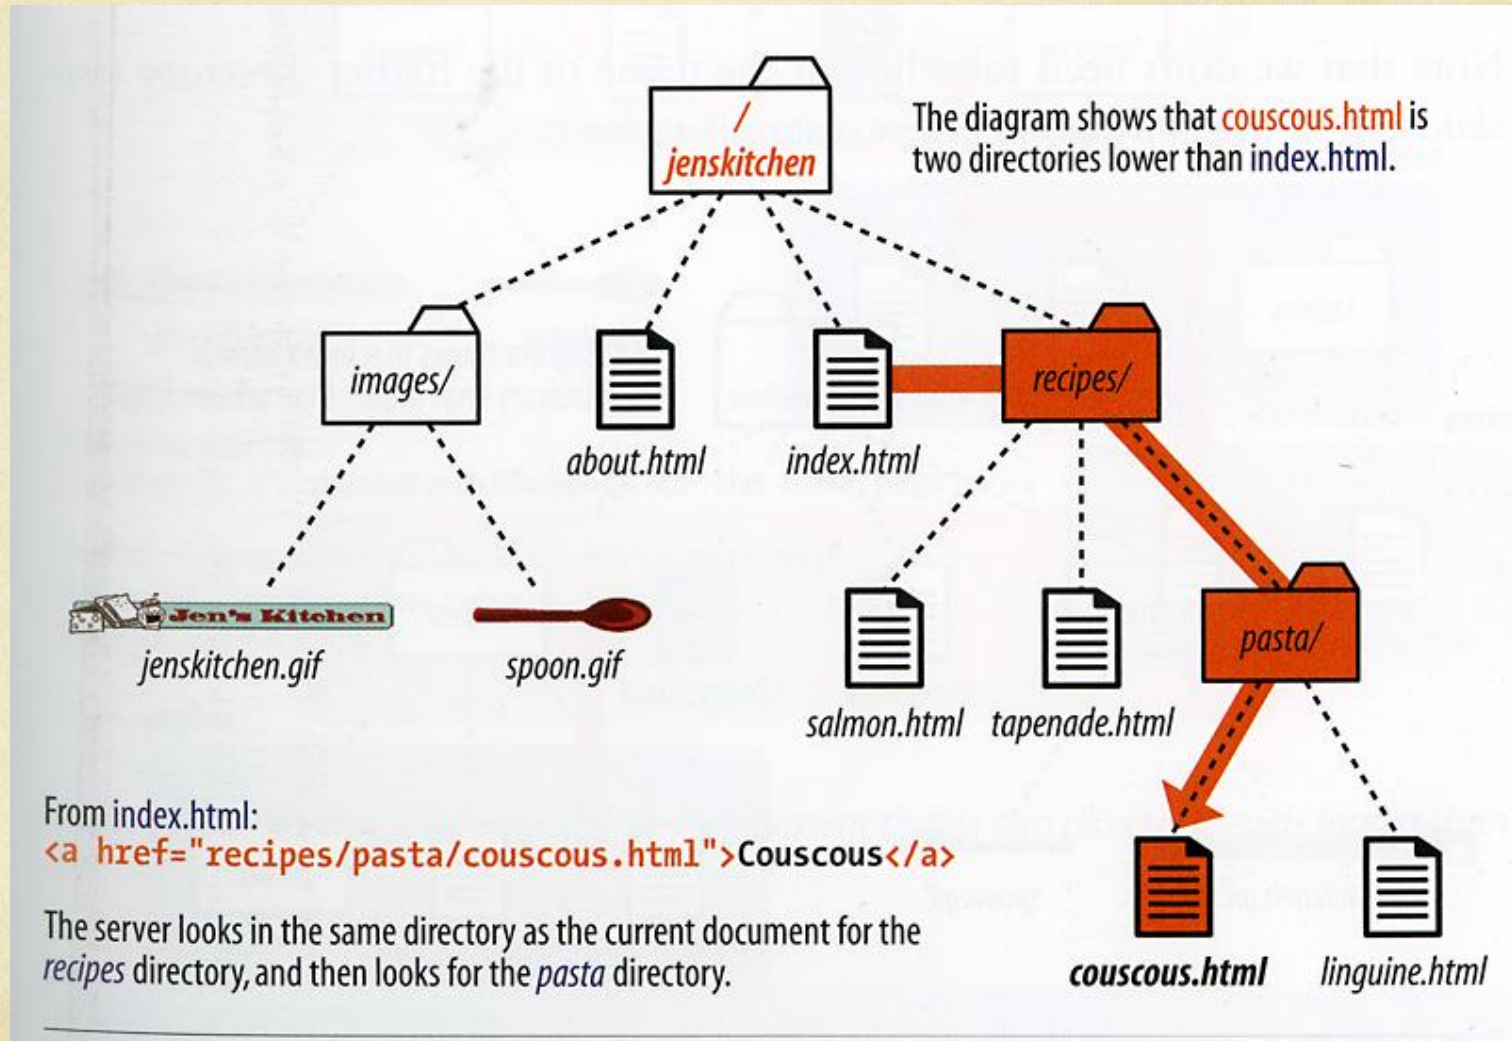

# Linking to a Lower Directory

```
<a href= "recipes/pasta/couscous.html">Couscous</a>
```

- The previous example linked one directory down.
- What if we want to link two directories down?
- For example, suppose want to link to `couscous.html`.
- This is inside the directory `pasta`, which is inside the directory `recipes`, which is located in the current directory.
- We do this by simply separating the directory names with forward slashes.

# Linking to a Higher Directory

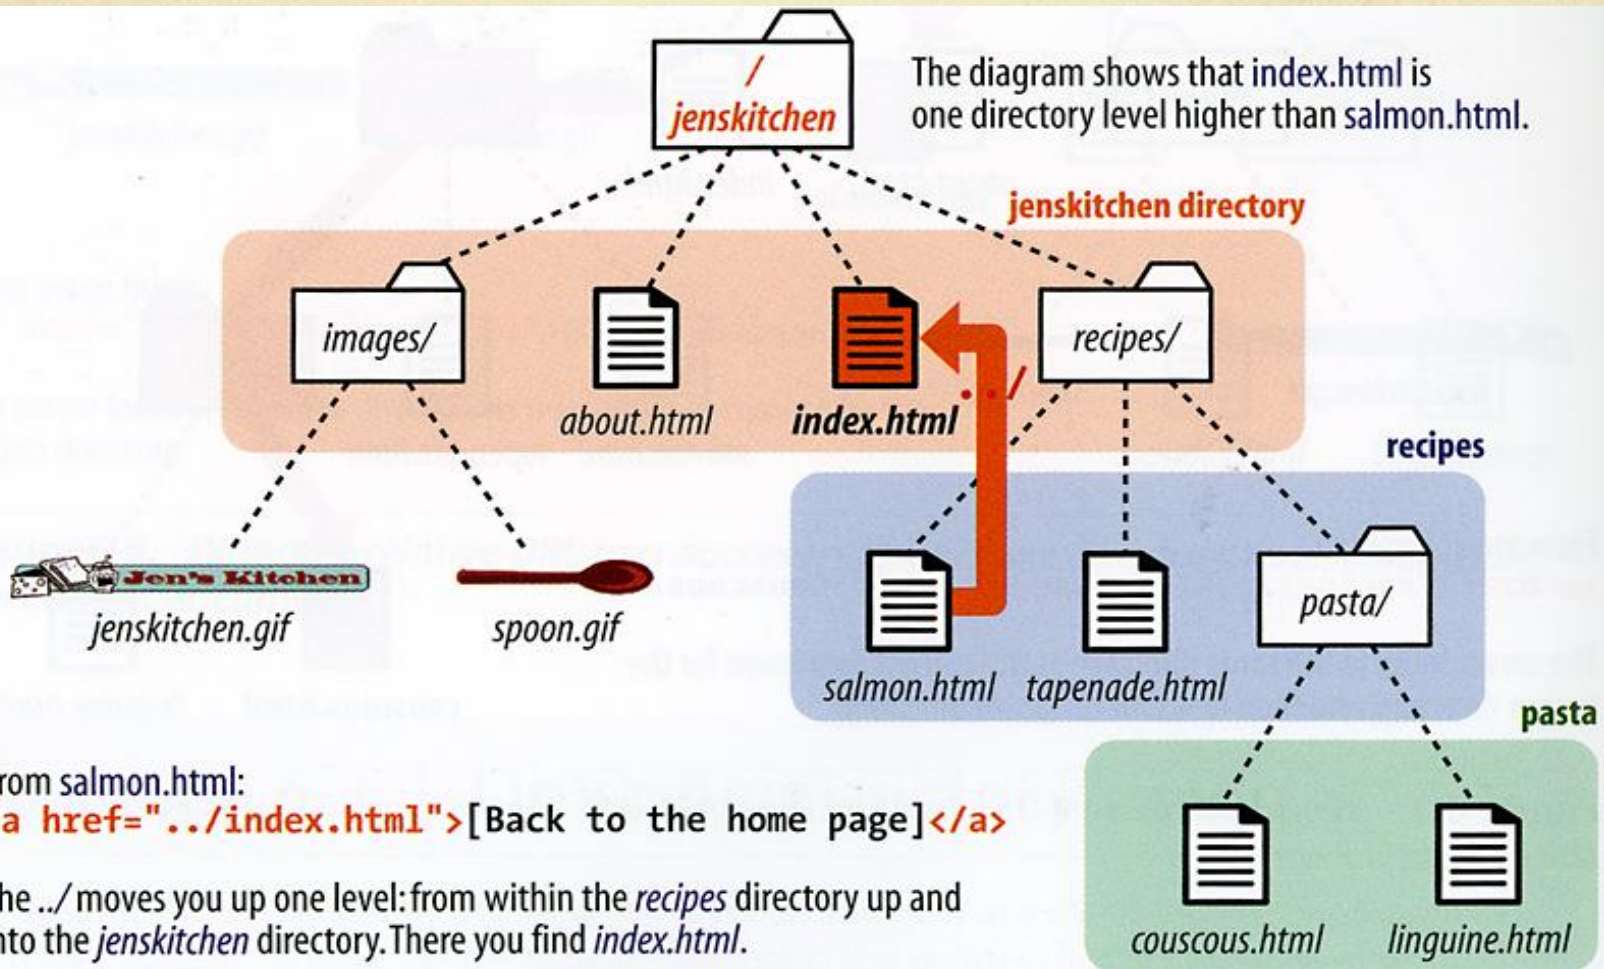

# Linking to a Higher Directory

```
<a href="../../index.html">[Back to the home page]</a>
```

- What if we want to link back up?
- Suppose, for example we wanted to link from the page `salmon.html` back to the `index.html` page.
- To do this we use the “dot-dot-slash” convention.
- When we begin a pathname with `../` it is the same as telling the browser to go “back up on directory level”.
- It’s like clicking the “Up” button on Windows Explorer.
- So let’s see how this works by making a link from `salmon.html` to `index.html`.

# Linking Within Your Own Site

# Linking to a Higher Directory

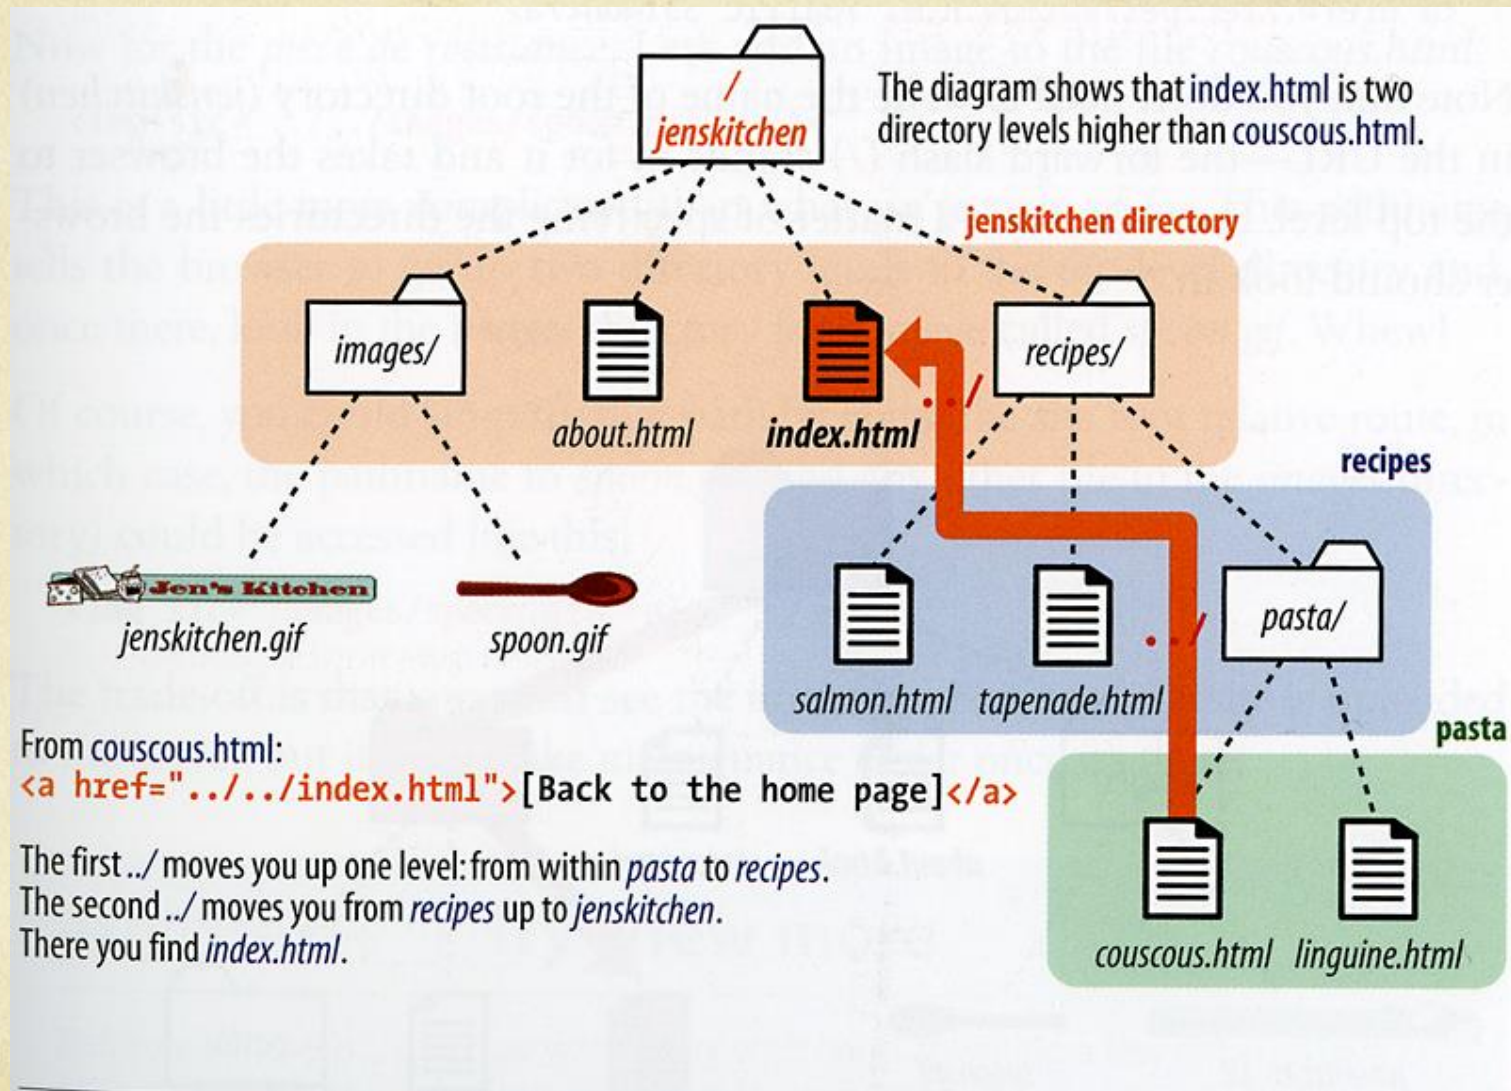

- What if we want to link all the way back to the home page from `couscous.html`?
- This has to go back two directory levels.
- This is done by simply adding the `../` twice.
- So a link on the `couscous.html` page to `index.html` would be:

```
<a href="../../index.html">[Back to the  
home page]</a>
```

- The first `../` backs us up to the `recipes` folder and the second one back us up to the `jenskitchen` folder.

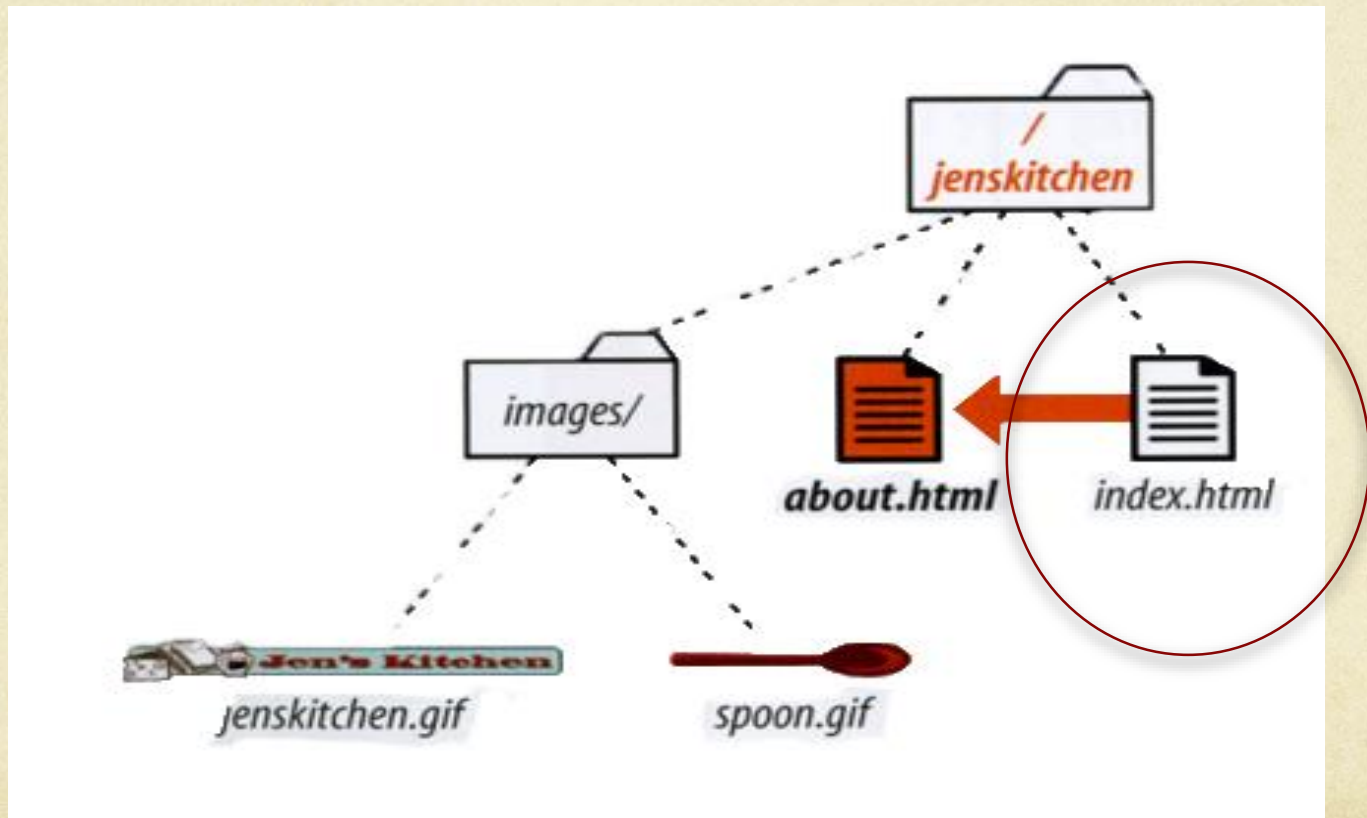

# Linking to a Higher Directory

# Linking Within Your Own Site

`<a href="about.html">About Page</a>`

The background of the slide is a light beige or cream color, resembling aged paper. It is decorated with numerous black ink splatters and dots of varying sizes. A large, dense cluster of black ink is located on the left side, with several smaller, isolated dots scattered across the rest of the page.

# Images as Links

# Images as links

- To make an image a link simply add an anchor <a> element around your image
- E.g.

```
<a href="index.html"></a>
```

- That's it !
- NOTE:  
have no space between >< or you'll get spaces as links too...  
This is one time where SPACES matter a lot !!!!!!!!!!!!!!!

email Links

@

# email Links

- Here's something handy.
- Can use **mailto** protocol to put link to email address appearing in web page
- When user clicks email link, their email program will boot up with new mail message started to that email address
  - If device web page being viewed on has an email application ...
- e.g.

```
<a href="mailto:marie.brennan@itb.ie">
```

```
Contact Marie</a>
```

Path to IMAGES in other directories

## Path to IMAGES in other directories

- The `src` attribute of the `img` element works the same way as the `href` attribute of the anchor element.
- For example suppose we want to include the image `jenskitchen.gif` on the `index.html` page.
- This would be:

``

- What if we wanted to display image `spoon.gif` from the page `couscous.html`?

``

# Summary

- So far we have covered the basic structure of a webpage
- We have used the elements needed to add content
- We have added images
- We have made an image as a link
- In the lab next week you will create 2 pages with all of the above elements and link the 2 pages together
- What next?????

```
body {  
  font: x-small  
  background:  
  color: black  
  margin: 0;  
  padding: 0;
```

- We need to start formatting the default elements on the screen
- We need to add some colour
- We need to change the layout of the screen  
How?????? CSS  
Cascading Style Sheets

## CSS - what?

- Cascade Style Sheets
- Defines how to display HTML elements (fonts, size, colors, background images, border, styles)
- Add to HTML **5**
- Stored in CSS files
- All browsers support CSS
- Defined by the World Wide Web consortium (W<sub>3</sub>C)

CSS Website Example

<http://www.csszengarden.com/>

# What is CSS?

- **Cascading**: Multiple styles can overlap in order to specify a range of style from a whole web site down to a unique element. Which style gets applied pertains to the rules of CSS cascading logic.
- **Styl**e: CSS deals specifically with the **presentation** domain of designing a web page (color, font, layout, etc).
- **Sheet**: Normally, CSS is a file **separate** from the HTML file – linked to the HTML file through its `<head>` (exceptions apply).

## CSS - why???

- **Advantages**

- Saves time editing (define once on the element, next time the elements will automatically defined)
- Page load faster
- Easy maintenance
- Superior styles to HTML (much wider array of attributes)

# syntax

A CSS rule has two main parts: a selector, and one or more declarations

The selector is the HTML element you want to style.

- Each declaration consists of a property and a value.
- The property is the style attribute you want to change. Each property has a value.

## how to ??

### Text editors

- Notepad/WordPad for Windows; TextEdit for Mac
- Dreamweaver has a function embedded into the program.

### Comments

```
/* This is for CSS. */
```

### Grouping

```
h1, h2, h3 {color: blue;}
```

### Applying multiple properties

```
h1 {color: blue;  
    font-size: 150%;  
    font-family: arial, Helvetica, "sans serif";  
}
```

## inline and internal styles

```
<html>

  <head>
    <title>Project One</title>
    <style type="text/css">
      body {background-color: #ff0000;}
      p {color: blue; margin-left:20px;}
    </style>
  </head>

  <body style="background-color: #ff0000;">
    <p style="color:blue;margin-left:20px ;">
      This is a red page.
    </p>
  </body>

</html>
```

## external style (1)

- Create a text file and save as .css
- Create a link in HTML document
- The css style sheet contains only styles

## external style – where to put it?

style.css

Changes in the external style sheet will effect all HTML documents

HTML documents linking to the same style sheet

# Linking an external file in HTML 5

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="utf-8">
  <title> Black Goose Bistro </title>

  <style>
    @import "goose.css";
  </style>
</head>

<body>

<h1> Black Goose Bistro</h1>
<h2> The Restaurant</h2>
<p> The Black Goose Bistro offers casual lunch and dinner fare in a hip atmosphere</p>
<h2> Catering</h2>
<p> You have fun ... <em> we'll handle the cooking</em>. Black Goose Catering can handle even
<h2> Location and Hours </h2>
<p> Seekonk, Massachusetts;
Monday though Thursday 11am to 9pm, Friday and Saturday, 11am to midnight </p>
</body>
</html>
```

# The CSS

```
body {  
    background-color: lightblue;  
    font-family: monospace;  
}  
  
h1 {  
    color: red;  
}  
  
h2 {  
    font-variant: small-caps;  
}
```

## Summary / Conclusions ...

- Many text properties you can control
  - Font / size / color / bold / italics etc.
- Use the BOOK or a good reference chart
  - It's hard to remember them all ...

## cascade order

Styles can be specified:

- Inside an HTML element (in-line)
- Inside the head section of an HTML page (internal)
- In an external CSS style sheet (external)

# Next week

- Lab – Linking pages
